

## **Equine Herpesvirus Myeloencephalopathy (EHM)**

Disease Name: Equine Herpesvirus Myeloencephalopathy

**Disease Type:** EHM is a neurologic syndrome caused by the EHV-1 virus. While EHV-1 is common in equine populations, the neurologic form of disease is rare. In extremely rare cases, EHV-4 can also cause EHM.

**Transmission:** EHV-1 is spread from horse to horse through contact with nasal discharge or inhalation of aerosolized respiratory droplets. Horses can also contract the virus by coming into contact with contaminated surfaces such as stalls, water, feed, tack, and transport vehicles. Humans can spread the virus from horse to horse through contaminated hands and clothing.

**Frequency:** Although EHV-1 and EHV-4 are a relatively common cause of a mild respiratory disease (also called equine rhinopneumonitis), EHM, the neurologic form, is rare. It is unknown why this virus develops into neurologic disease in only some horses.

**Incubation period:** Ranges from 5 to 6 days. Horses can shed the virus during the incubation period.

**Carrier status:** Infected horses become lifelong carriers and can intermittently shed the virus even when showing no clinical signs. It is thought that most horses become infected with EHV early in life. While horses with EHM can be very contagious during an active outbreak situation, there are no documented cases of EHM horses causing additional cases of EHM after they have recovered and have been cleared by testing, quarantine, or both.

**Latency:** The virus can remain latent for the lifespan of the horse. Reactivation and viral shedding can occur periodically, especially during stressful events such as travel, illness, etc.

**Severity:** EHM is a life-threatening condition. Survival of affected horses is around 50%.

## **Clinical signs:**

- Fever- This virus typically causes a biphasic (two phase) fever. The horse will have fever on day 1 or 2 and again on day 6 or 7. Neurological signs may not present until the second fever. Some horses may not develop a fever.
- Nasal discharge
- Depression
- Incoordination
- Hind limb weakness
- Loss of tail tone
- Loss of bladder tone- urine dribbling or inability to urinate
- Dog sitting position
- Leaning against a fence or wall to maintain balance
- Recumbency (inability to rise)

Equine Disease Communication Center: Disease Factsheet

**Diagnosis:** EHV-1 is diagnosed by PCR testing of nasal swab and whole blood samples. Horses that test positive for EHV-1 <u>and</u> have neurologic signs are considered positive for EHM.

**Treatment:** Supportive care and rest. Non-steroidal anti-inflammatory medications, such as phenylbutazone (Bute) or flunixin meglumine (Banamine) are used to control fever and improve appetite. Antivirals, heparin, and intense supportive care (urinary cathetization, sling, etc) are also often utilized for EHM cases.

**Prognosis:** Prognosis for horses with EHM is guarded, with approximately 50% survival. Horses that survive may or may not have residual neurologic deficits.

**Prevention**: There is currently no vaccine labeled for the prevention of the neurologic form (EHM). Management practices for preventing EHV-related disease includes maintaining current vaccinations on all horses on the property, practicing biosecurity while traveling and showing, and quarantining any new horses (or horses returning to a farm after travel) for at least 21 days before integration into the farm herd. Horses at shows should have their temperatures monitored twice daily.

**Biosecurity:** Biosecurity practices for EHV focus on minimizing horse-horse transmission through aerosol particles from nasal discharge or through contaminated surfaces including people, clothing, feed and water, implements, and stalls. This includes extensive disinfection of surfaces and equipment that come in contact with infected horses, as well as isolation of any horse that tests positive on nasal swab or blood.
